THE 50-WEEK STUDY

Does losing Bitcoin's 50-week average mean another crash?

Every historical break, the market splits, recovery pullbacks and post-midterm selloffs behind our carousel.

13
Previous weekly breaks

8 of 13
Higher one week later

7 of 13
Lower four weeks later

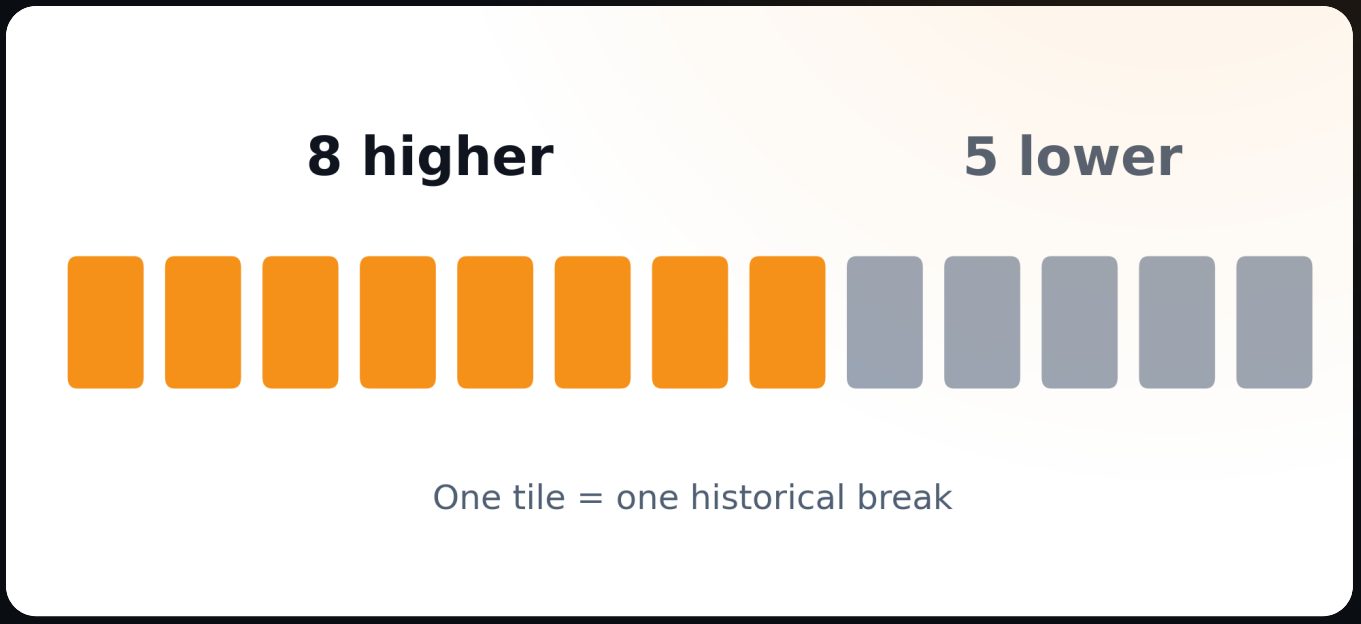

July remains a possible bottom. The November 8 weekly close is the latest completed observation in this study.

@bitcoin.daily

START WITH THE WEEKLY CLOSE

A BREAK IS A WARNING. NOT A VERDICT.

Bitcoin closed Sunday at **$74,742.52**, below its **$75,492.20** 50-week simple moving average. It ended a seven-week run above the line. The prior weekly reclaim was September 20.

The average uses the last 50 completed weekly closing prices. A new break counts only when the prior week closed on or above its own average and the next week closes below its own average. An intraday dip does not qualify.

8 of 13 previous breaks were higher one week later. That initial bounce did not settle the longer-term outcome. Four weeks later, seven were lower.

Complete Monday-to-Sunday UTC weeks. The open November 9 week is excluded. Our first valid 50-week average is in August 2012; the first qualifying break is August 2014.

THE FULL SAMPLE

WHAT FOLLOWED ALL 13 BREAKS

AFTER THE BREAK	HIGHER / SAMPLE	MEDIAN PRICE CHANGE
1 week	8 / 13	+4.8%
4 weeks	6 / 13	-4.3%
12 weeks	6 / 13	-1.0%
26 weeks	7 / 13	+23.5%
52 weeks	7 / 12	+92.9%

A positive final return can hide a large selloff along the way. The median lowest price in the next four weeks was **11.0% below the break-week close**. Across the next 12 weeks, the median lowest price was **29.4% below it**.

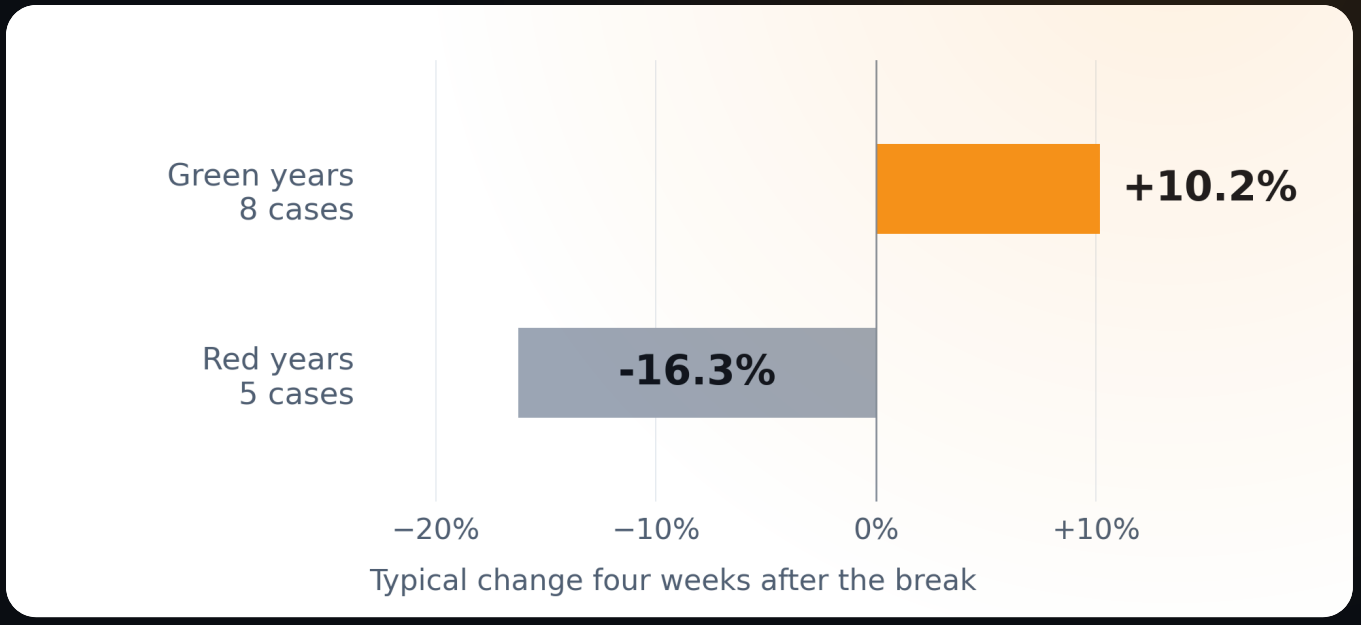

All 13 historical cases eventually closed back above their own 50-week average. The median wait was **two weeks**, but the slowest took **62 weeks**. Seven regained it within four weeks.

Those waits include repeated breaks during the same recovery. A one-week reclaim did not guarantee the next break was avoided.

Median means the middle observation. Forward returns use later weekly closes. Lowest-price comparisons use daily lows in the following full weeks and exclude the signal week. The November 2025 case has no completed 52-week outcome yet. These are price outcomes, not strategy returns.

GREEN YEARS AND RED YEARS

THE BACKDROP CHANGED THE OUTCOME

CALENDAR-YEAR GROUP	CASES	HIGHER AFTER 4W	MEDIAN 12W
Green year	8	6 of 8	+22.2%
Red year	5	0 of 5	-25.4%

All five red-year cases were lower four weeks later. The typical four-week change was **-16.3%**, compared with **+10.2%** in green years.

The red-year cases were August 2014, May 2018, January 2022, April 2022 and November 2025. Multiple breaks can come from the same year and selloff.

These groups use completed full-calendar-year returns. They describe past environments and do not classify unfinished 2026 or produce a forecast probability.

BULL PHASE VERSUS BEAR PHASE

A SEPARATE CYCLE SPLIT

COMPLETED CYCLE PHASE	CASES	HIGHER AFTER 4W	MEDIAN 4W	MEDIAN 12W
Low to next peak	7	6 of 7	+11.7%	+26.8%
Peak to final low	5	0 of 5	-16.3%	-19.1%
Latest unresolved cycle	1	0 of 1	-6.4%	-25.4%

Bull phases run from the final lows of January 2015, December 2018 and November 2022 to the next cycle peaks. Bear phases run from the preceding peaks to those final lows.

December 2021 sits in a green calendar year but in the completed bear phase after the November peak. That is why calendar years and cycle phases give different counts.

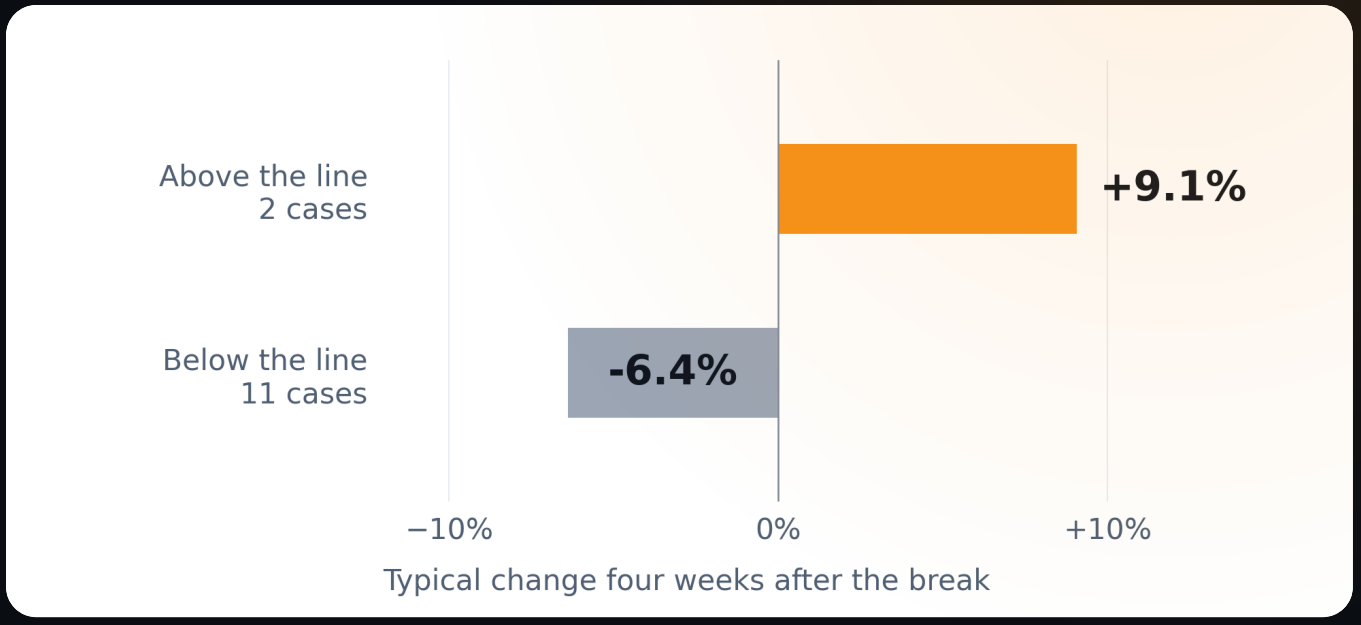

The November 2025 break is kept separate because its cycle has no confirmed final low. The new November 2026 break also remains pending.

The completed-cycle split depends on final peaks and lows identified later. July 2026 is a candidate, so we cannot treat the current break as a confirmed post-bottom bull-phase event.

Bull and bear here are the exact peak-to-low and low-to-peak intervals above, not discretionary labels based on a chart's appearance. The seven bull-phase signals are also clustered, not seven independent cycles.

THE DAILY 200-DAY AVERAGE

ABOVE THE DAILY LINE. ONLY TWO PRECEDENTS.

PRICE AT WEEKLY BREAK	CASES	HIGHER AFTER 4W	MEDIAN 4W	MEDIAN 12W
Above 200-day SMA	2	2 of 2	+9.1%	+31.7%
Below 200-day SMA	11	4 of 11	-6.4%	-11.8%

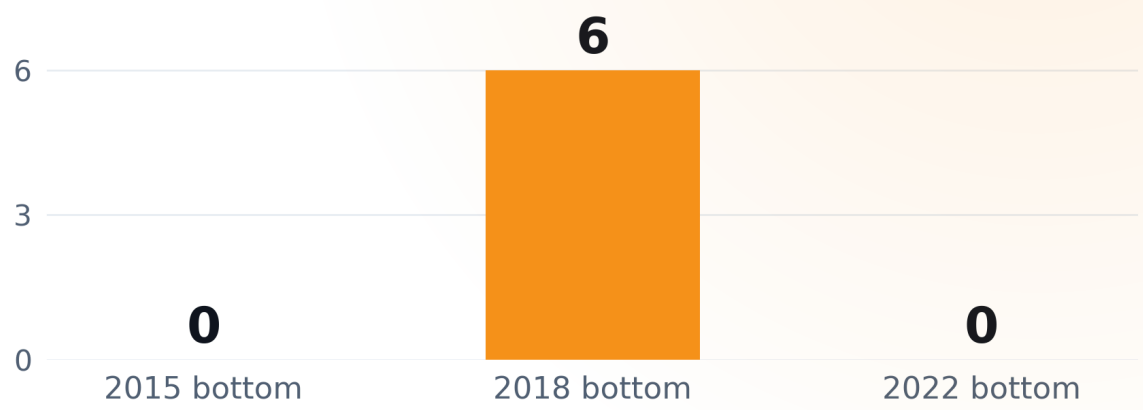

Sunday's close was still above the **$73,170.61** daily 200-day average. This comparison uses the last 200 daily closing prices through the signal Sunday.

The only two earlier matches were **May 10 and May 24, 2020**. Their four-week gains were 11.7% and 6.5%. Both came from the same recovery, just two weeks apart.

Two overlapping observations cannot establish a reliable probability for this week. This is the daily 200-day average, separate from the 200-week average.

AFTER A FINAL BOTTOM

THE 2018 RECOVERY LOST IT SIX TIMES

Weekly breaks before the previous high returned

From the known December 2018 low until the old all-time high was regained, Bitcoin lost the weekly 50-MA **six times**. The 2015 and 2022 recoveries had no qualifying breaks in their matching low-to-old-high windows.

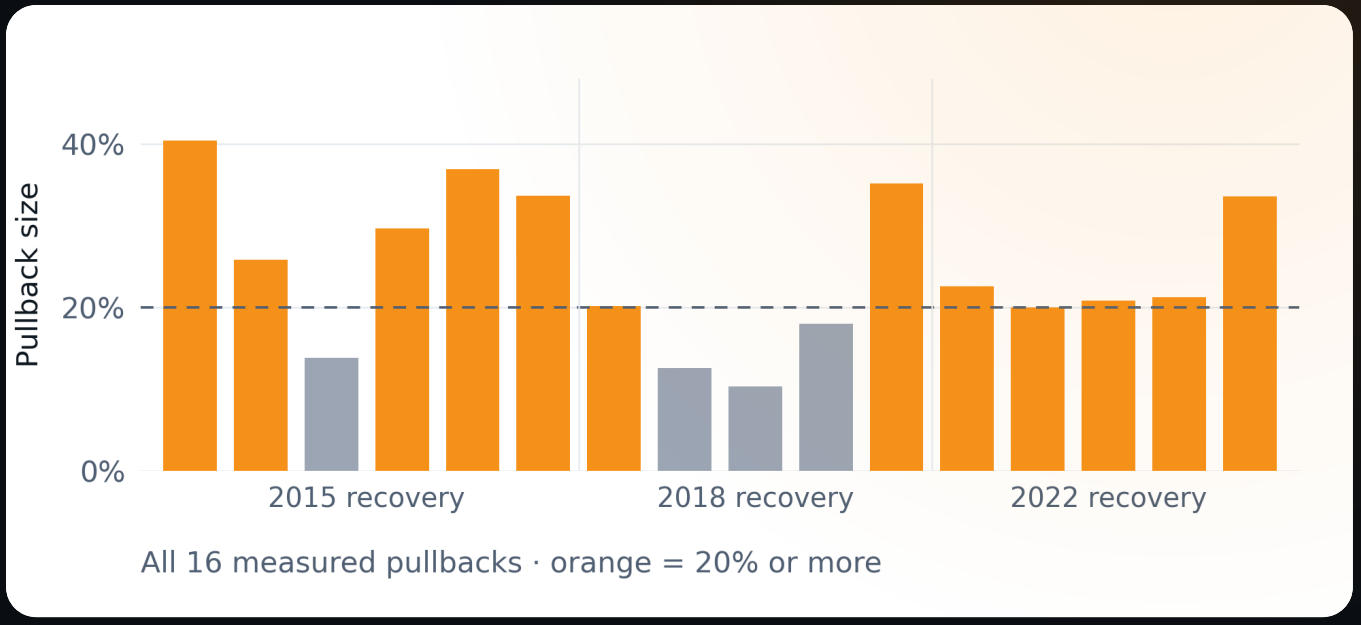

The first was **November 24, 2019**. It regained the line the next week and was 8.7% higher after four weeks and 43.5% higher after 12. Then the COVID crash took it 44.3% below that original signal close within 26 weeks.

The December 2018 low of $3,122.28 still held against the March 2020 low of $3,850. A recovery can suffer a major setback without making a new cycle low.

All six breaks belong to one recovery. Because this group starts at lows later known to be final, survival of those lows is not an independent success rate. An early 2012 composite-data comparison is outside this primary Bitstamp sample.

THE RECOVERY PULLBACK STUDY

EVEN A REAL BOTTOM LEAVES ROOM TO FALL

Our separate hand-measured study recorded **16 pullback legs** across the 2015, 2018 and 2022 recoveries. **12 reached at least 20%**. The median decline was **21.925%**, rounded to about 22% in the carousel.

These are multiple legs inside three recoveries, including later pullbacks. They are not 16 first pullbacks after 16 separate bottoms. The 2015 measured sequence begins at the August higher low, rather than January's final bottom.

Some early recovery pullbacks happened while price was still below the weekly 50-MA. They could not register a fresh loss of a line that had not yet been regained.

Manual legs use the original Bitfinex 2015 and Binance 2018/2022 measurements. Current dollar comparisons use Bitstamp. A separate weekly high/low algorithm has an ordering problem around January 2015 and is not used as verified first-rally evidence here.

THE PRICE MAP

WHAT THOSE DROPS WOULD MEAN NOW

20% comparison

$69,900

Typical comparison

$68,200

Historical comparisons, not price targets

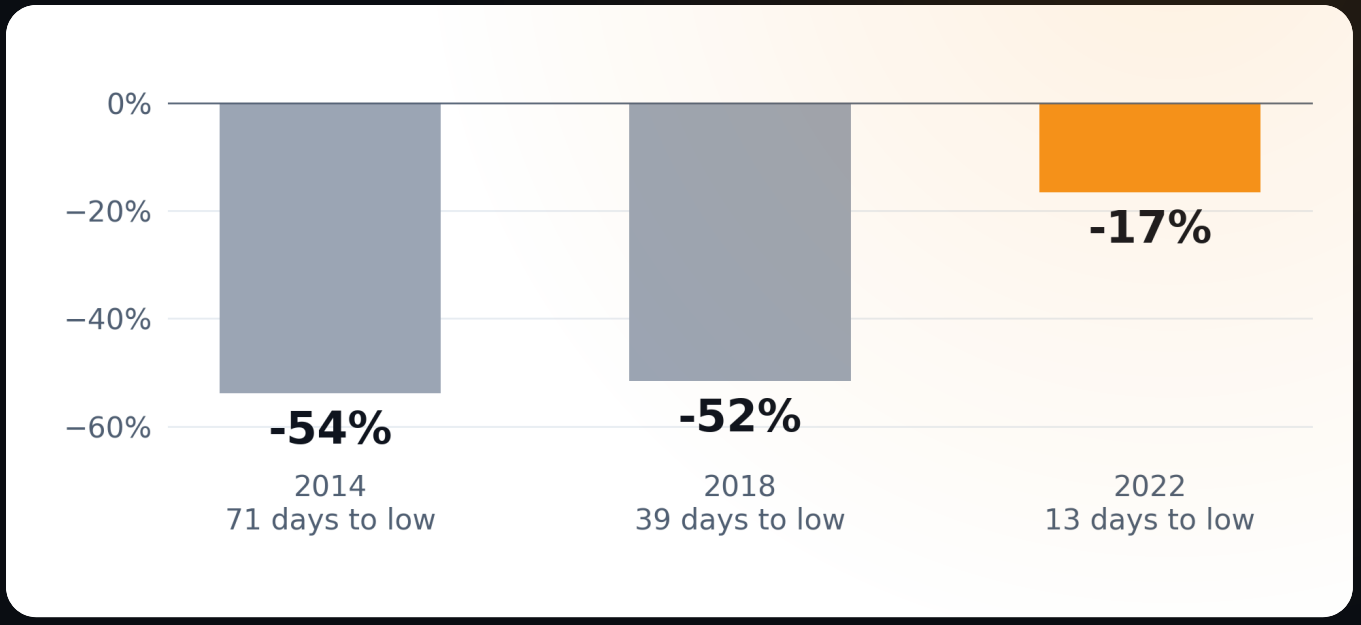

REFERENCE OR COMPARISON	BTC PRICE
September 21 high	$87,373.64
20% below that high	$69,898.91
21.925% below that high	$68,216.97
50% July-to-September retracement	$72,554.14
July 1 candidate low	$57,734.63

A move into **$68k-$70k** would fit the size of many recovery pullbacks we measured and would still be above July's low. That makes it a comparison worth watching, not proof that price must reach that area or stop there.

The 50% retracement uses the July 1 low of $57,734.63 and September 21 high of $87,373.64. The November 8 200-week SMA was $67,754.71. Moving averages change with new data; all quoted levels are dated snapshots.

THE POST-MIDTERM COMPARISON

THE SELLING DID NOT END ON ELECTION DAY

MIDTERM	FURTHER FALL	DAYS TO FINAL LOW	ONE-YEAR RETURN
2014	-53.8%	71	+23.6%
2018	-51.6%	39	+44.9%
2022	-16.6%	13	+92.1%

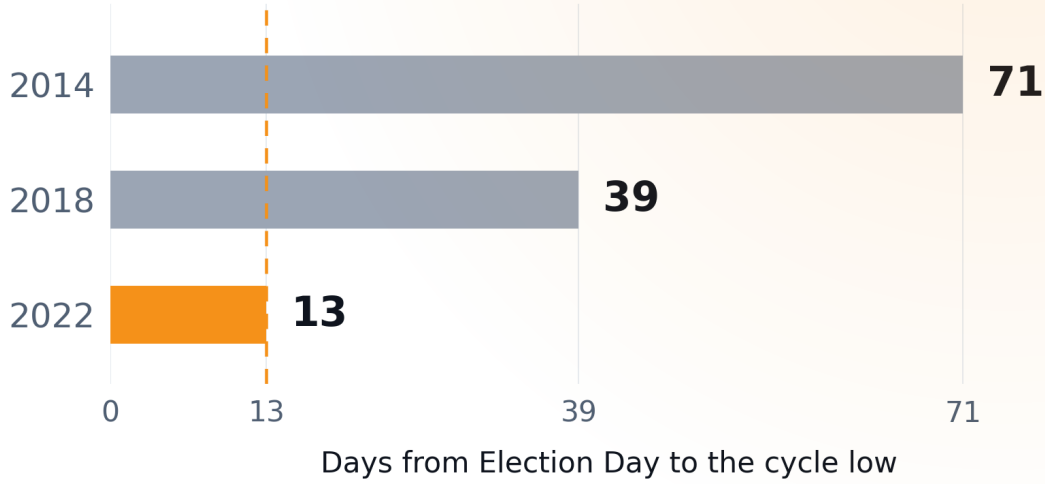

Each fall starts at the **Election Day UTC closing price** and ends at the later final cycle low. This is a different starting point from the September-high pullback comparison.

All three were higher one year after Election Day, but first suffered more selling. This does not isolate an election effect from the bear market already underway.

The three completed Bitcoin midterms are 2014, 2018 and 2022. 2010 is excluded. Daily closes and intraday lows are different measurements. Election-date close sources and final-low dates are retained in our study tables.

OUR CURRENT BOTTOM WINDOW

NOVEMBER 16 REMAINS THE DEADLINE

Our working bottom window remains **October 5 through November 16**. Applying the three historical post-midterm waits to November 3 gives November 16, December 12 and January 13, 2027.

Only the shortest wait lands inside the current window. The other two took longer. The historical comparison does not confirm a November 16 bottom or extend our window.

If July proves to be the final cycle bottom, our autumn timing window was late. A November decline into $68k-$70k would not fix that timing call because it would still leave July's lower price intact.

The weekly MA, recovery pullbacks and midterm history describe overlapping Bitcoin price cycles. We do not multiply them into a combined probability or call July confirmed.

EVERY HISTORICAL BREAK

THE FULL 13-CASE RECORD

SIGNAL SUNDAY	4W CLOSE	12W CLOSE	LOWEST IN 12W	WEEKS TO REGAIN
2014-08-17	-4.3%	-26.6%	-44.7%	62
2018-05-27	-16.3%	-11.8%	-21.4%	49
2019-11-24	+8.7%	+43.5%	-7.0%	1
2019-12-15	+15.0%	+12.9%	-9.7%	1
2019-12-29	+16.3%	-21.3%	-47.9%	2
2020-03-08	-15.7%	+17.6%	-52.1%	8
2020-05-10	+11.7%	+26.8%	-6.3%	1
2020-05-24	+6.5%	+36.6%	-1.0%	1
2021-07-18	+48.0%	+72.2%	-7.8%	1
2021-12-19	-7.7%	-19.1%	-29.4%	1
2022-01-02	-19.9%	-1.0%	-30.4%	12
2022-04-10	-19.2%	-54.2%	-58.2%	49
2025-11-16	-6.4%	-25.4%	-36.4%	44

Forward returns start at the break-week close. The lowest-price column is the deepest intraday low over the following 12 completed weeks. Regain means the first later weekly close on or above that week's own 50-week average.

The November 8, 2026 event is the fourteenth detected break and is pending. All 13 historical cases are retained, including repeated whipsaws and losses. This is not a set of independent trades.

SOURCES AND DEFINITIONS

HOW WE MEASURED IT

Primary prices are Bitstamp BTC/USD daily OHLC from August 18, 2011 through November 8, 2026. Weekly bars require seven daily observations, Monday through Sunday UTC. The 50-week simple moving average includes the signal week.

Returns compare the signal weekly close with the exact weekly close 1, 4, 12, 26 or 52 weeks later. Future lows exclude the signal week. Incomplete horizons stay pending rather than being treated as zero.

Context groups retain repeated signals and overlapping forward windows. Completed calendar years and completed cycle phases are retrospective descriptions. The daily 200-day split uses information available on the signal Sunday.

Recovery windows run from each known final intraday cycle low to the first daily high reaching the old cycle peak. Manual pullback legs retain the source venues and measurement dates of the original three-recovery study.

No trading strategy is tested here. Price changes exclude execution, position size, fees, slippage, taxes and exit decisions. A historical frequency is not a calibrated probability for today.

Our read is conditional. Losing the weekly line raises concern, but it has also happened during a recovery. We watch the completed closes and July's low without treating one indicator as a bottom verdict.

Prepared November 9, 2026 from the saved November 8 completed-week snapshot. More research and the primary price-data source are linked below.
