THE CURRENT CHART

What if Bitcoin has not bottomed after all?

Bitcoin reached $67,500 overnight, about 23% below September's $87,374 high. The 20% to 22% comparison zone we mapped on Tuesday has been exceeded.

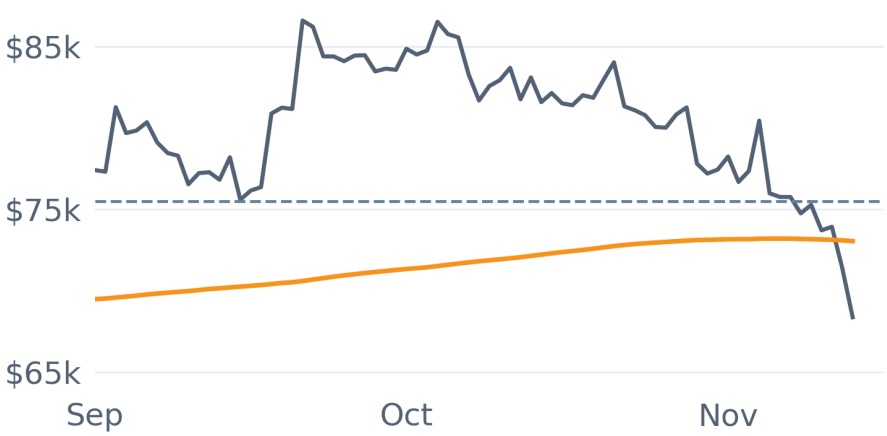

This edition matches the November 13 carousel. It covers the current trend, the recovery pullback study, a recovery that failed, and a cycle low that survived another crash.

All current charts use the approved November 13 snapshot. They are dated observations, not live quotes. July remains a possible bottom.

THE TREND HAS WEAKENED

The averages above price

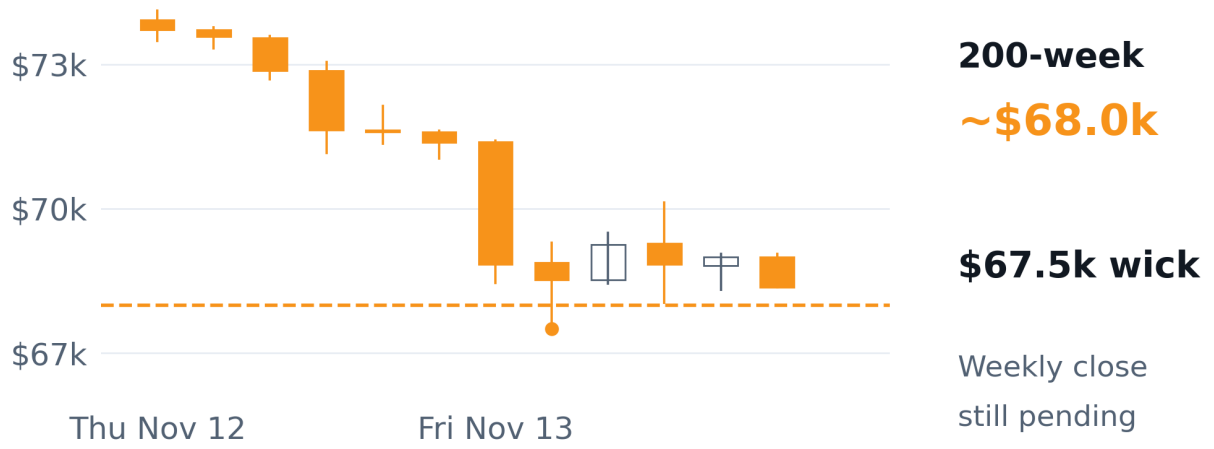

The last completed weekly candle, November 8, closed below the 50-week simple moving average. Its completed-week reference is about $75,492. The forming daily 200-day average was about $73,037 at the approved snapshot.

Both sit above the bounce. A recovery through these areas would repair part of the trend damage, but a reclaim alone would not prove the final bottom is in.

The daily curve and the completed-week reference use different timeframes. The 50-week line is not the 50-day average.

THE NEARBY TEST

The 200-week average

4-hour candles · Line uses this week’s forming 200-week average

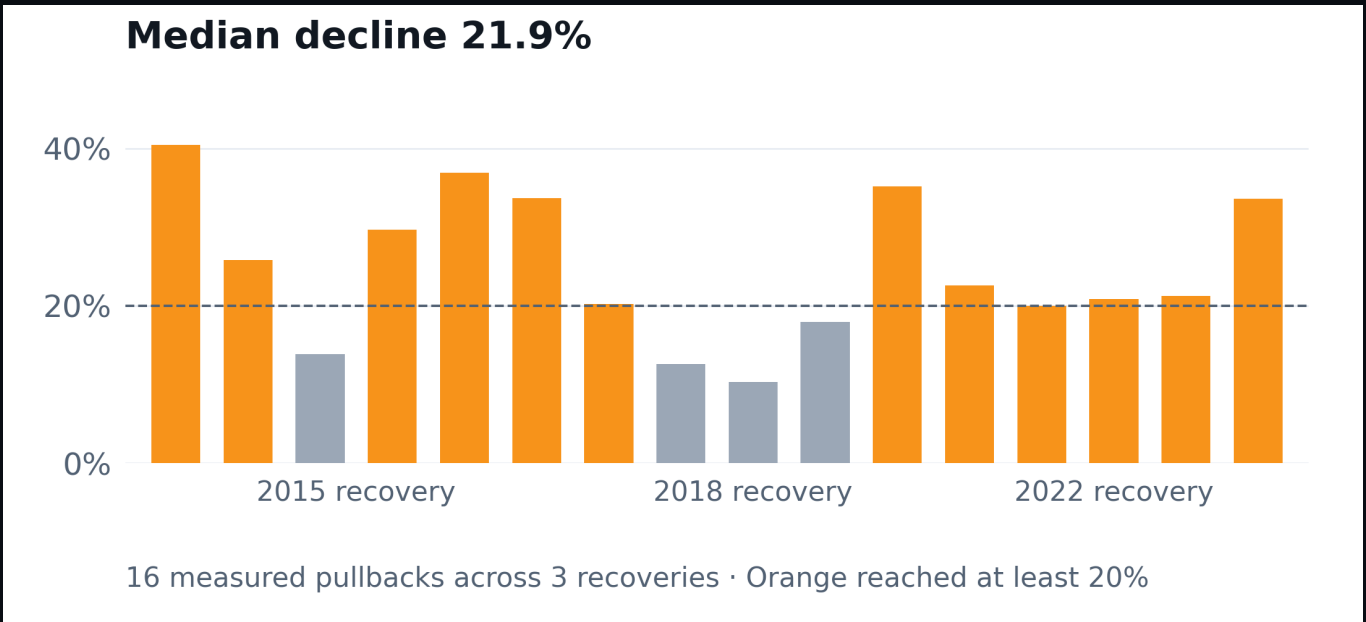

The forming 200-week average was $67,992, close to $68k. The overnight $67,500 low briefly traded below it. At the snapshot, price was back above it and the weekly close was still pending.

An intraday trade below an average and a completed weekly close below it are different observations. We cannot count an unfinished candle as a confirmed weekly breakdown.

The chart uses real four-hour candles. The horizontal line is this week's developing 200-week average; it can change before the week closes.

HISTORICAL RECOVERY CORRECTIONS

What the 16 pullbacks show

12 of 16 selected pullbacks reached at least 20%. The median was 21.925%, rounded to 21.9%. The observations come from three completed recovery paths after the 2015, 2018 and 2022 cycle lows.

These were recoveries whose lows ultimately held. That makes them useful comparisons for correction size, but does not establish that July belongs in the same group. The 16 legs are not 16 independent bottom events or forecast odds.

A 23% decline fits within the observed range. It does not tell us the decline is finished.

THE FULL SELECTED SAMPLE

Every recovery pullback

Recovery after low	Measured decline
2015	40.42%
2015	25.80%
2015	13.86%
2015	29.66%
2015	36.94%
2015	33.65%
2018	20.20%
2018	12.56%
2018	10.34%
2018	17.96%
2018	35.15%
2022	22.58%
2022	20.00%
2022	20.87%
2022	21.27%
2022	33.58%

These are the selected measured legs in our recovery study, not a census of every daily decline. Multiple legs share the same cycle. The earlier chart rounded the 2018 17.96% leg to 18%; this table preserves the stored value.

WHEN A RECOVERY FAILS

The February 2018 rebound

Daily closes · Dots mark intraday extremes · One failed-recovery example

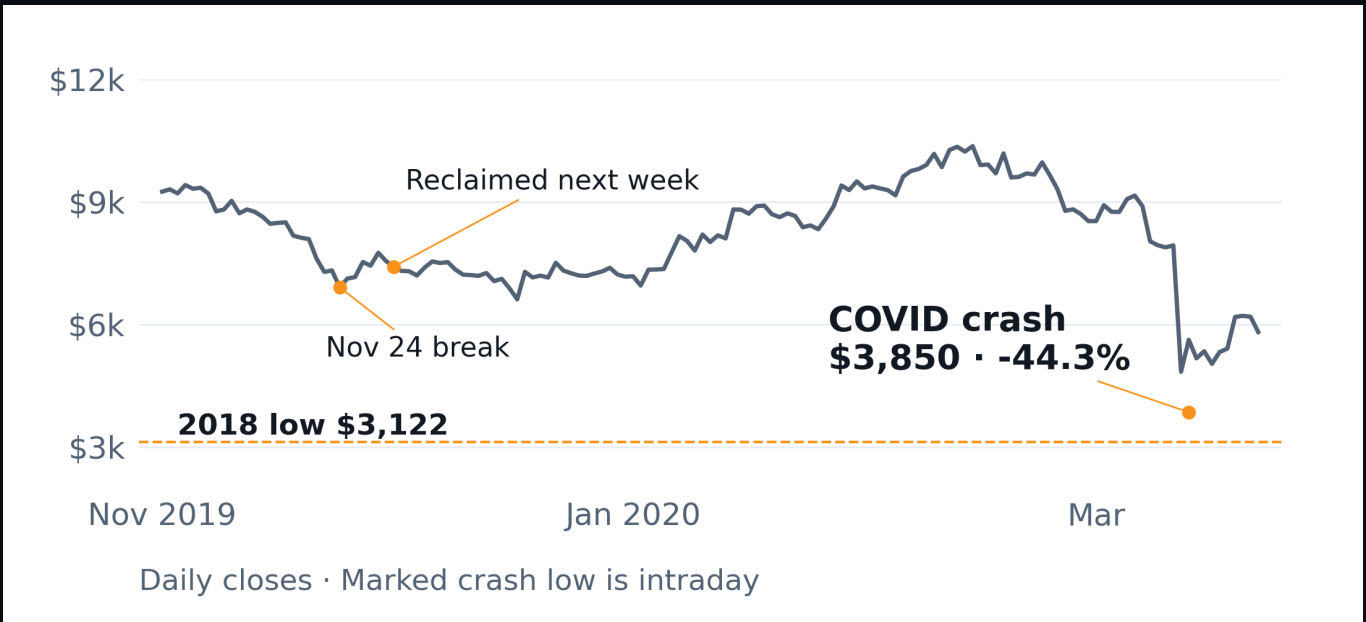

Bitcoin rebounded from a $5,921 February low to $11,780 that month, nearly doubling. By December, price reached $3,122. The apparent February bottom did not survive.

A large rally can occur before a bear market makes its final low. This is one failed-recovery example, not a matched forecast for the current market.

The line shows daily closes. Dots mark intraday extremes: February 6 low $5,920.72, February 20 high $11,780, December 15 low $3,122.28.

WHEN THE CYCLE LOW HOLDS

The 2019 breakdown

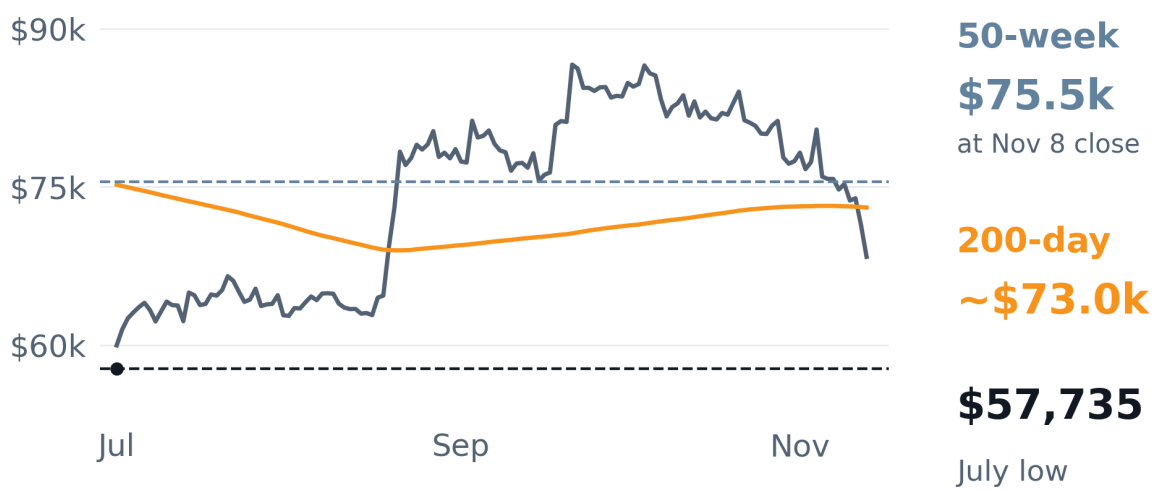

Bitcoin lost the 50-week average on November 24, 2019, then reclaimed it the next week. The March 2020 COVID crash later reached $3,850, 44.3% below that $6,908.36 breakdown close.

The December 2018 cycle low of $3,122.28 still held. A trend break and another severe selloff do not always erase the prior cycle low. A quick reclaim also does not rule out a later crash.

This counterexample and the failed 2018 recovery show different outcomes. Two illustrations do not estimate the probability of either outcome today.

THE CURRENT BOTTOM CASE

What would invalidate July?

Daily closes · A new low below July would invalidate that bottom

July's low is $57,734.63, displayed as $57,735. From $67,500, reaching it would require another 14.47% decline, rounded to 14.5%. The denominator is the overnight low, not the earlier high.

Losing the daily 200-day and weekly 50-week averages weakens the recovery case. A new low below July would invalidate July as the final bottom. Until then, it remains possible rather than confirmed.

The 20% and 22% comparisons from $87,373.64 are $69,898.91 and $68,151.44. They have already been exceeded. Historical correction sizes are comparison levels, not guaranteed support.

HOW TO USE THE STUDY

Three checks from here

1. Separate the bounce from the trend. Track whether price can recover the daily 200-day average and the weekly 50-week average. A rally while below them leaves the recovery under pressure.

2. Wait for the weekly close. The 200-week average is near the overnight low, but the forming weekly candle can still change. Record the wick and the closing result separately.

3. Keep the July case conditional. A break below $57,735 invalidates that particular bottom. Holding above it does not confirm the low or guarantee an immediate rally.

Reading the research. Current daily, four-hour and weekly calculations are frozen to the approved November 13 chart snapshot at 21:20 UTC. Weekly averages use 50 or 200 weekly closes; the 200-day average uses daily closes. The current daily and weekly values include the unfinished candle.

Historical figures come from our archived daily OHLC data and the source-reviewed recovery-leg table. The 2018 and 2019 examples are descriptive case studies. The current recovery sample is conditioned on lows that ultimately held and is not a stand-alone trading strategy or a calibrated probability model.

The November 10 edition is archived at /guides/files/the-first-pullback-study-2026-11-10.pdf. The October 9 edition is also retained; market levels in both editions are outdated.

A 20% fall followed by a 20% rise still leaves a 4% loss: $100 becomes $80, then $96. Compare prices from the same reference point when judging a recovery.
